MAMMALIAN LYSOPHOSPHATIDIC ACID ACYLTRANSFERASE

This is a continuation-in-part of U.S. application serial No. 08/618,651, filed March 19, 1996.

Technical Field of the Invention

5 The present invention provides polypeptides having lysophosphatidic acid acyltransferase (LPAAT) activity and polynucleotides encoding polypeptides having LPAAT activity. The present invention further provides for isolation and production of polypeptides involved in phosphatidic acid metabolism and signaling in mammalian cells, in particular, the production of purified forms of LPAAT.

10

Background of the Invention

 LPAAT, also referred to as 1-acyl sn-glycerol-3-phosphate acyltransferase (EC 2.3.1.51), is known to catalyze the acylation of lysophosphatidic acid (LPA) to phosphatidic acid (PA) by acylating the sn-2 position of LPA with a fatty acid acyl-chain moiety. LPA and PA, while originally identified as intermediates in lipid biosynthesis (Kent, *Anal. Rev. Biochem.* 64:315-343, 1995), have more recently been identified as phospholipid signaling molecules that affect a wide range of biological responses (McPhail et al., *Proc. Natl. Acad. Sci. USA* 92:7931-7935, 1995; Williger et al., *J. Biol. Chem.* 270:29656-29659, 1995; Moolenaar, *Curr. Opin. Cell Biol.* 7:203-210, 1995).

20 Cellular activation in monocytic and lymphoid cells is associated with rapid upregulation of synthesis of phospholipids (PL) that includes PA, diacylglycerol (DAG) and glycan phosphatidylinositol (PI). PAs are a molecularly diverse group of phospholipid second messengers coupled to cellular activation and mitogenesis (Singer et al., *Exp. Opin. Invest. Drugs* 3:631-643, 1994). PA can be generated through hydrolysis of phosphatidylcholine (PC) (Exton, *Biochim. Biophys. Acta* 1212:26-42, 1994) or glycan PI (Eardley et al., *Science* 251:78-81, 1991; Merida et al., *DNA Cell Biol.* 12:473-479, 1993), through phosphorylation of DAG by DAG kinase (Kanoh et al., *Trends Biochem. Sci.*

25

15:47-50, 1990) or through acylation of LPA at the SN2 position (Bursten et al., *Am. J. Physiol.* 266:C1093-C1104, 1994).

Compounds that block PA generation and hence diminish lipid biosynthesis and the signal involved in cell activation are therefore of therapeutic interest in, for example, the areas of inflammation and oncology as well as obesity treatment. Therefore, compounds that block LPAAT activity have a similar therapeutic value.

The genes coding for LPAAT have been isolated in bacteria (Coleman, *Mol. Gen. Genet.* 232:295-303, 1992), in yeast (Nagiec et al., *J. Biol. Chem.* 268:22156-22163, 1993) and in plants (Brown et al., *Plant Mol. Biol.* 26:211-223, 1994; and Hanke et al., *Eur J. Biochem.* 232:806-810, 1995; Knutzon, et al., *Plant Physiol.* 109: 999-1006, 1995). Moreover, two human isoforms of LPAAT have been reported (West, et al., *DNA Cell Biol.* 6: 691-701, 1997). These isoforms are denominated LPAAT α and LPAAT β (West, et al., *DNA Cell Biol.* 6: 691-701, 1997) and are described herein. There remains, however, a need for the isolation of additional mammalian LPAATs, which can be used, for example, to screen for compounds that inhibit LPAAT activity.

Summary of the Invention

The present invention provides cDNA sequences, polypeptide sequences, and transformed cells for producing isolated recombinant mammalian LPAAT. The present invention provides four polypeptides corresponding to human LPAAT isoforms. These polypeptides are designated hLPAAT α , hLPAAT β , hLPAAT γ 1, hLPAAT γ 2, and hLPAAT δ . The invention further provides fragments of these polypeptides which are biologically active, *i.e.*, which retain LPAAT activity. LPAAT activity is defined catalyzing acylation of lysophosphatidic acid (LPA) to phosphatidic acid (PA), specifically by acylating the sn-2 position of LPA with a fatty acid acyl-chain moiety.

The present invention further provides nucleic acid sequences encoding hLPAAT α , hLPAAT β , hLPAAT γ 1, hLPAAT γ 2, and hLPAAT δ and polynucleotides coding for biologically active fragments of hLPAAT α , hLPAAT β , hLPAAT γ 1, hLPAAT γ 2, and hLPAAT δ . The invention further provides "biologically active" polynucleotide fragments, which connotes polynucleotide fragments which encode polypeptides having LPAAT activity. The invention further provides purified LPAATs and antisense oligonucleotides for modulation of expression of the genes coding for

LPAAT polypeptides. Assays for screening test compounds for their ability to inhibit LPAATs are also provided.

The present invention includes the following polynucleotides coding for hLPAAT α , hLPAAT β , hLPAAT γ 1, hLPAAT γ 2, and hLPAAT δ . The invention provides the DNA sequences of: SEQ ID NO. 1 which encodes for hLPAAT α ; SEQ ID NO. 7,
5 which encodes hLPAAT β ; Figure 9, which encodes hLPAAT γ 1 Figure 10, which encodes hLPAAT γ 2; and Figure 11, which encodes and hLPAAT δ .

The invention further includes the polypeptides for hLPAAT α , hLPAAT β , hLPAAT γ 1, hLPAAT γ 2, and hLPAAT δ , specifically, the amino acid sequences of: SEQ
10 ID NO. 2, which represents hLPAAT α ; SEQ ID NO. 8, which represents hLPAAT β ; Figure 9, which represents hLPAAT γ 1; Figure 10, which represents hLPAAT γ 2; and Figure 11, which represents hLPAAT δ .

The invention further comprises biologically active fragments of the amino acid sequences of SEQ ID NO. 2, SEQ ID NO. 8, Figure 9, Figure 10, and Figure 11 or
15 nucleotide fragments of SEQ ID NO. 1, SEQ ID NO. 7, Figure 9, Figure 10, and Figure 11 which encode biologically active LPAAT. The invention further includes polynucleotides which due to the degeneracy of the genetic code encode a polypeptide of SEQ ID NO. 2, SEQ. ID NO. 8, Figure 9, Figure 10, and Figure 11. The invention further includes polynucleotides capable of hybridizing to the nucleic acid sequences of SEQ ID NO. 1,
20 SEQ ID NO. 7, Figure 9, Figure 10, and Figure 11, under high stringency conditions, and which are biologically active.

Also provided by the present invention are vectors containing a DNA sequence encoding a mammalian LPAAT enzyme in operative association with an expression control sequence. Host cells, transformed with such vectors for use in producing
25 recombinant LPAAT, are also provided with the present invention. The inventive vectors and transformed cells are employed in a process for producing recombinant mammalian LPAAT. In this process, a cell line transformed with a DNA sequence encoding LPAAT in operative association with an expression control sequence, is cultured. The claimed process may employ a number of known cells as host cells for expression of the LPAAT
30 polypeptide, including, for example, mammalian cells, yeast cells, insect cells and bacterial cells. The present invention further provides transformed cells that expresses active mammalian LPAAT.

The present invention further provides methods for identifying compounds that increase or decrease LPAAT activity, *i.e.*, acylation of LPA to PA. Because PA concentration is involved in numerous cellular pathways, compounds that increase or decrease acylation of LPA to PA are useful in regulating a number of cellular pathways.

5 Such compounds can be used, for example, to augment trilineage hematopoiesis after cytoreductive therapy or to inhibit inflammation following hypoxia and reoxygenation injury (*e.g.*, sepsis, trauma, and ARDS). Moreover, the present invention contemplates the use of such compounds in an *in vitro* or *in vivo* context.

The present invention further includes: An isolated polynucleotide encoding a polypeptide having Lysophosphatidic Acid Acyltransferase (LPAAT) activity, comprising
10 a nucleotide sequence selected from the group consisting of:

(a) the DNA sequence of Figure 9, Figure 10, or Figure 11 and biologically active fragments thereof; and

(b) a DNA sequence which encodes the polypeptide of Figure 9, Figure 10, or
15 Figure 11 and biologically active fragments thereof.

An isolated polypeptide having LPAAT activity, comprising the amino acid sequence of Figure 9, Figure 10, or Figure 11 and biologically active fragments thereof.

A method for screening one or more compounds to determine whether the one or more compounds increases or decreases LPAAT activity, comprising:

20 (a) contacting the polypeptide of the present invention with one or more substrates for the polypeptide and with the one or more compounds; and

(b) measuring whether the LPAAT activity of the polypeptide is increased or decreased by the one or more compounds.

A method of expressing the polypeptide of the present invention, comprising:

25 (a) introducing into a cell a polynucleotide comprising a nucleotide sequence selected from the group consisting of:

(i) the DNA sequence of Figure 9, Figure 10, or Figure 11 and biologically active fragments thereof; and

(ii) a DNA sequence which encodes the polypeptide of Figure 9, Figure 10,
30 or Figure 11 and biologically active fragments thereof,

wherein the polynucleotide is operably linked to a promoter; and

(b) maintaining or growing said cell under conditions that result in the expression of the polypeptide.

An isolated polynucleotide encoding a polypeptide having Lysophosphatidic Acid Acyltransferase (LPAAT) activity, comprising a DNA sequence capable of hybridizing
5 under high stringency conditions to the complement of the DNA sequences, (a) or (b), described above, and which encodes a polypeptide having LPAAT activity.

Brief Description of the Drawings

Figure 1 shows the DNA sequence of the cDNA insert of pZplat.11 encoding
10 hLPAAT α .

Figure 2 shows amino acid sequence alignment of the human LPAAT α coding sequence, the yeast LPAAT coding sequence, *E. coli* LPAAT coding sequence, and the maize LPAAT coding sequence. This comparison shows that human LPAAT α has the greatest extended homology with yeast or *E. coli* LPAAT than with the plant LPAAT.

15 Figure 3 shows the DNA sequence of the cDNA insert pSP.LPAT3 encoding hLPAAT β . The nucleotide sequence analysis and restriction mapping of the cDNA clone revealed a 5' untranslated region of 39 base pairs and an open reading frame encoding a 278 amino acid polypeptide that spans positions 40-876. It also shows a 3' untranslated region of 480 base pairs from pSP.LPAT3. The initiation site for translation was localized
20 at nucleotide positions 40-42 and fulfilled the requirement for an adequate initiation site (Kozak, *Critical Rev. Biochem. Mol. Biol.* 27:385-402, 1992).

Figure 4 shows the sequence of the hLPAAT β 278 amino acid open reading frame. The amino acid sequence was used as the query sequence to search for homologous sequences in protein databases. Search of the database based on Genbank Release 92
25 database from the National Center for Biotechnology Information (NCBI) using the blastp program showed that this protein was most homologous to yeast, bacterial and plant LPAATs.

Figure 5 shows amino acid sequences alignment of human LPAAT β coding sequence, human LPAAT α coding sequence, yeast LPAAT coding sequence, bacterial (*E. coli*, *H. influenzae*, and *S. typhimurium*) LPAAT coding sequences, and plant (*L. douglassi*
30 and *C. nucifera*) LPAAT coding sequences, revealing that the human LPAAT coding

sequences have a much more extended homology with the yeast or the bacterial LPAAT than with the plant LPAAT.

Figure 6 shows a comparison of LPAAT activity in A549 cells transfected with pCE9.LPAAT1 DNA, or no DNA using a TLC (thin layer chromatography) assay. These data are described in more detail in examples 3 and 4.

Figures 7 and 8 show a comparison of the production of TNF (Figure 7) and IL-6 (Figure 8) between A549 cells transfected with pCE9.LPAAT1 and control A549 cells after stimulation with IL-1 β and murine TNF. These data show A549 overexpressing LPAAT produces >5 fold more TNF and >10 fold more IL-6 relative to untransfected A549 cells, suggesting that over expression of LPAAT enhances the cytokine signaling response in cells.

Figure 9 shows the DNA and the translated sequence of LPAAT γ 1.

Figure 10 shows the DNA and the translated sequence of LPAAT γ 2.

Figure 11 shows the DNA and the translated sequence of LPAAT δ .

Figure 12 shows the LPAAT amino acid sequence alignment for human LPAAT γ 1, γ 2, and δ .

Figure 13 compares the LPAAT activity in ECV304 cells stably transfected with the expression plasmids for LPAAT α (pCE9.LPAAT- α), LPAAT β (pCE9.LPAAT- β) DNA, LPAAT γ 1 (pC9LPT γ 1), LPAAT δ (pC2LPT δ), or the control vector (pCE9).

Detailed Description of the Invention

The present invention provides isolated LPAAT polypeptides and isolated polynucleotides encoding LPAAT polypeptides. The term "isolated," in this context, denotes a polypeptide or polynucleotide essentially free of other polypeptides or nucleic acid sequences, respectively, or of other contaminants normally found in nature.

The invention includes biologically active LPAAT and biologically active fragments thereof. As used herein, the term "biologically active" in the context of LPAAT activity refers to the ability to catalyze the acylation of lysophosphatidic acid (LPA) to phosphatidic acid (PA) by acylating the sn-2 position of LPA with a fatty acid acyl-chain moiety.

The term "expression product" as used throughout the specification refers to materials produced by recombinant DNA techniques.

The present invention contemplates modification of the hLPAAT α , hLPAAT β , hLPAAT γ 1, hLPAAT γ 2, and hLPAAT δ polypeptide sequences. Such modifications may be deliberate, as by site-directed mutagenesis, or may be spontaneous. All of the polypeptides produced by these modifications are included herein as long as the acyltransferase activity of LPAAT is present.

For example, the present invention contemplates the deletion of one or more amino acids from the polypeptide sequence of the hLPAAT α , hLPAAT β , hLPAAT γ 1, hLPAAT γ 2, and hLPAAT δ to create deletion variants. This deletion can be of one or more amino or carboxy terminal amino acids or one or more internal amino acids.

The present invention further contemplates one or more amino acid substitutions to the polypeptide sequence of hLPAAT α , hLPAAT β , hLPAAT γ 1, hLPAAT γ 2, and hLPAAT δ to create substitutional variants. The present invention contemplates that such substitutional variants would contain certain functional alterations, such as stabilizing against proteolytic cleavage. Yet, it is understood that such variants retain their acyltransferase activity.

Substitutions preferably are conservative, that is, one amino acid is replaced with one of similar shape and charge. Conservative substitutions are well known in the art and include, for example, the changes of: alanine to serine; arginine to lysine; asparagine to glutamine or histidine; aspartate to glutamate; cysteine to serine; glutamine to asparagine; glutamate to aspartate; glycine to proline; histidine to asparagine or glutamine; isoleucine to leucine or valine; leucine to valine or isoleucine; lysine to arginine, glutamine, or glutamate; methionine to leucine or isoleucine; phenylalanine to tyrosine, leucine or methionine; serine to threonine; threonine to serine; tryptophan to tyrosine; tyrosine to tryptophan or phenylalanine; and valine to isoleucine or leucine.

The present invention further contemplates the insertion of one or more amino acids to the polypeptide sequences of hLPAAT α , hLPAAT β , hLPAAT γ 1, hLPAAT γ 2, and hLPAAT δ to create an insertional variant. Examples of such insertional variants include fusion proteins such as those used to allow rapid purification of the polypeptide and also can include hybrid polypeptides containing sequences from other proteins and polypeptides which are homologues of the inventive polypeptide. For example, an insertional variant could include portions of the amino acid sequence of the polypeptide from one species, together with portions of the homologous polypeptide from another species. Other

insertional variants can include those in which additional amino acids are introduced within the coding sequence of the polypeptides. These typically are smaller insertions than the fusion proteins described above and are introduced, for example, to disrupt a protease cleavage site.

5 Polypeptides of the present invention can be synthesized by such commonly used methods as t-BOC or FMOC protection of alpha-amino groups. Both methods involve step-wise syntheses whereby a single amino acid is added at each step starting from the C terminus of the peptide (Coligan et al., *Current Protocols in Immunology*, Wiley Interscience, Unit 9, 1991). In addition, polypeptide of the present invention can also be
10 synthesized by solid phase synthesis methods (e.g., Merrifield, *J. Am. Chem. Soc.* 85:2149, 1962; and Steward and Young, *Solid Phase Peptide Synthesis*, Freeman, San Francisco pp. 27-62, 1969) using copolyol (styrene-divinylbenzene) containing 0.1-1.0 mM amines/g polymer. On completion of chemical synthesis, the polypeptides can be deprotected and cleaved from the polymer by treatment with liquid HF 10% anisole for about 15-60 min at
15 0 °C. After evaporation of the reagents, the peptides are extracted from the polymer with 1% acetic acid solution, which is then lyophilized to yield crude material. This can normally be purified by such techniques as gel filtration of Sephadex G-15 using 5% acetic acid as a solvent. Lyophilization of appropriate fractions of the column will yield a homogeneous polypeptide or polypeptide derivatives, which are characterized by such
20 standard techniques as amino acid analysis, thin layer chromatography, high performance liquid chromatography, ultraviolet absorption spectroscopy, molar rotation, solubility and quantitated by solid phase Edman degradation.

The invention also provides polynucleotides which encode the hLPAAT polypeptides of the invention. As used herein, "polynucleotide" refers to a polymer of
25 deoxyribonucleotides or ribonucleotides in the form of a separate fragment or as a component of a larger construct.

Polynucleotide sequences of the invention include DNA, RNA and cDNA sequences. Preferably, the polynucleotide sequences encoding hLPAAT are the sequences of: SEQ ID NO. 1 for hLPAAT α ; SEQ ID NO. 7 for LPAAT β ; Figure 9 for hLPAAT γ 1;
30 Figure 10 for hLPAAT γ 2; and Figure 11 for hLPAAT δ . DNA sequences of the present invention can be obtained by several methods. For example, the DNA can be isolated using hybridization procedures which are known in the art. Such hybridization procedures

include, for example, hybridization of probes to genomic or cDNA libraries to detect shared nucleotide sequences, antibody screening of expression libraries to detect shared structural features, such as a common antigenic epitope, and synthesis by the polymerase chain reaction (PCR).

5 Hybridization procedures are useful for screening of recombinant clones by using labeled mixed synthetic oligonucleotide probes, wherein each probe is potentially the complete complement of a specific DNA sequence in a hybridization sample which includes a heterogeneous mixture of denatured double-stranded DNA. For such screening, hybridization is preferably performed on either single-stranded DNA or denatured double-
10 stranded DNA. Hybridization is particularly useful for detection of cDNA clones derived from sources where an extremely low amount of mRNA sequences relating to the polypeptide of interest are present. Using stringent hybridization conditions directed to avoid non-specific binding, it is possible to allow an autoradiographic visualization of a specific cDNA clone by the hybridization of the target DNA to that single probe in the
15 mixture, which is its complement (Wallace et al. *Nucl. Acid Res.* 9:879, 1981). Stringent conditions preferably include high stringency conditions. See, for example, Maniatis et al, *Molecular Cloning (A Laboratory Manual)*, Cold Spring Harbor Laboratory, pages 387-389, 1982. One such high stringency hybridization condition is, for example, 4 X SSC at 65 °C, followed by washing in 0.1 X SSC at 65 °C for thirty minutes. Alternatively,
20 another high stringency hybridization condition is in 50% formamide, 4 X SSC at 42 °C.

 The development of specific DNA sequences encoding hLPAAT can also be obtained by isolation of double-stranded DNA sequences from the genomic DNA, chemical manufacture of a DNA sequence to provide the necessary codons for the polypeptide of interest, and *in vitro* synthesis of a double-stranded DNA sequence by
25 reverse transcription of mRNA isolated for a eukaryotic donor cell. In the latter case, a double-stranded DNA complement of mRNA is eventually formed which is generally referred to as cDNA. Of these three methods for developing specific DNA sequences for use in recombinant procedures, the isolation of genomic DNA isolates is the least common. This is especially true when it is desirable to obtain the microbial expression of
30 mammalian polypeptides due to the presence of introns.

 The synthesis of DNA sequences is frequently a method that is preferred when the entire sequence of amino acids residues of the desired polypeptide product is known.

When the entire sequence of amino acid residues of the desired polypeptide is not known, direct synthesis of DNA sequences is not possible and it is desirable to synthesize cDNA sequences. cDNA sequence isolation can be done, for example, by formation of plasmid- or phage-carrying cDNA libraries which are derived from reverse transcription of mRNA.

5 mRNA is abundant in donor cells that have high levels of genetic expression. In the event of lower levels of expression, PCR techniques are preferred. When a significant portion of the amino acid sequence is known, production of labeled single or double stranded DNA or RNA probe sequences duplicating a sequence putatively present in the target cDNA may be employed in DNA/DNA hybridization procedures, carried out on cloned copies of
10 the cDNA (denatured into a single-stranded form) (Jay et al., *Nucl. Acid Res.* 11:2325, 1983).

A cDNA expression library, such as lambda gt11, can be screened for hLPAAT α , hLPAAT β , hLPAAT γ 1, hLPAAT γ 2, and hLPAAT δ polypeptides using antibodies specific for hLPAAT α , hLPAAT β , hLPAAT γ 1, hLPAAT γ 2, and hLPAAT δ . Such antibodies can
15 be either polyclonally or monoclonally derived.

The polynucleotides of this invention include sequences that are degenerate as a result of the genetic code. The genetic code is described as degenerate because more than one nucleotide triplet, called a codon, can code for a single amino acid. The present invention contemplates the degeneracy of the genetic code and includes all degenerate
20 nucleotide sequences which encode hLPAAT α , hLPAAT β , hLPAAT γ 1, hLPAAT γ 2, and hLPAAT δ .

The present invention also includes polynucleotide sequences complementary to the polynucleotides encoding hLPAAT α , hLPAAT β , hLPAAT γ 1, hLPAAT γ 2, and hLPAAT δ . Specifically, the present invention includes antisense polynucleotides. An
25 antisense polynucleotide is a DNA or RNA molecule complementary to at least a portion of a specific mRNA molecule (Weintraub, *Sci. Amer.* 262:40, 1990). The invention embraces all antisense polynucleotides capable of inhibiting the expression of hLPAAT α , hLPAAT β , hLPAAT γ 1, hLPAAT γ 2, or hLPAAT δ . In a cell, the antisense polynucleotides hybridize to the corresponding mRNA, forming a double-stranded
30 molecule. The antisense polynucleotides interfere with the translation of mRNA since the cell cannot translate mRNA that is double-stranded. Antisense oligomers of about 15 nucleotides are preferred, since they are easily synthesized and are less likely to cause

problems than larger molecules when introduced into the target of hLPAAT α , hLPAAT β , hLPAAT γ 1, hLPAAT γ 2, or hLPAAT δ -producing cell. The use of antisense methods to inhibit translation of genes is known (e.g., Marcus-Sakura, *Anal. Biochem.* 172:289, 1988).

5 The present invention further includes allelic variations, i.e., naturally-occurring base changes in a species population which may or may not result in an amino acid change, to the polynucleotide sequences encoding hLPAAT α , hLPAAT β , hLPAAT γ 1, hLPAAT γ 2, or hLPAAT δ . The inventive polynucleotide sequences further comprise those sequences which hybridize under high stringency conditions (see, for example, Maniatis et
10 al, *Molecular Cloning (A Laboratory Manual)*, Cold Spring Harbor Laboratory, pages 387-389, 1982) to the coding regions or to the complement of the coding regions of hLPAAT α , hLPAAT β , hLPAAT γ 1, hLPAAT γ 2, or hLPAAT δ . One such high stringency hybridization condition is, for example, 4 X SSC at 65 °C, followed by washing in 0.1 X SSC at 65 °C for thirty minutes. Alternatively, another high stringency hybridization
15 condition is in 50% formamide, 4 X SSC at 42 °C.

 In addition, ribozyme nucleotide sequences that cleave hLPAAT α , hLPAAT β , hLPAAT γ 1, hLPAAT γ 2, and hLPAAT δ are included in this invention. Ribozymes are RNA molecules possessing an ability to specifically cleave other single-stranded RNA in a manner analogous to DNA restriction endonucleases. Through the modification of
20 nucleotide sequences which transcribe such RNAs, it is possible to engineer molecules that recognize specific nucleotide sequences in an RNA molecule and cleave it (Cech, *J. Amer. Med. Assn.* 260:3030, 1988).

 There are two basic types of ribozymes, *tetrahymena*-type (Hasselhoff, *Nature* 334:585, 1988) and "hammerhead-type". *Tetrahymena*-type ribozymes recognize
25 sequences which are four bases in length, while "hammerhead-type" ribozymes recognize base sequences 11-18 bases in length. The longer the recognition sequence, the greater the likelihood that the sequence will occur exclusively in the target mRNA species. Consequently, hammerhead-type ribozymes are preferable to *tetrahymena*-type ribozymes for inactivating a specific mRNA species.

30 Production of Polypeptides

 Polynucleotide sequences encoding hLPAAT α , hLPAAT β , hLPAAT γ 1, hLPAAT γ 2, and hLPAAT δ polypeptides of the invention can be expressed in either

prokaryotes or eukaryotes. Hosts can include microbial (bacterial), yeast, insect and mammalian organisms. Methods of expressing DNA sequences inserted downstream of prokaryotic or viral regulatory sequences in prokaryotes are known in the art (Makrides, *Microbio. Rev.* 60:512, 1996). Biologically functional viral and plasmid DNA vectors
5 capable of expression and replication in a eukaryotic host are known in the art (Cachianes, *Biotechniques* 15:255, 1993). Such vectors are used to incorporate DNA sequences of the invention. DNA sequences encoding the inventive polypeptides can be expressed *in vitro* by DNA transfer into a suitable host using known methods of transfection.

hLPAAT α , hLPAAT β , hLPAAT γ 1, hLPAAT γ 2, and hLPAAT δ sequences may be
10 inserted into a recombinant expression vector. The term "recombinant expression vector" refers to a plasmid, virus or other vehicle that has been manipulated by inserting or incorporating genetic sequences. Such expression vectors contain a promoter sequence which facilitates efficient transcription of the inserted genetic sequence of the host. The expression vector typically contains an origin of replication and a promoter, as well as
15 specific genes which allow phenotypic selection of the transformed cells. The DNA segment can be present in the vector, operably linked to regulatory elements, for example, a promoter (*e.g.*, T7, metallothionein I, or polyhedren promoters). Vectors suitable for use in the present invention include, for example, bacterial expression vectors, with bacterial promoter and ribosome binding sites, for expression in bacteria (Gold, *Meth. Enzymol.*
20 185:11, 1990), expression vector with animal promoter and enhancer for expression in mammalian cells (Kaufman, *Meth. Enzymol.* 185:487, 1990) and baculovirus-derived vectors for expression in insect cells (Luckow et al., *J. Virol.* 67:4566, 1993).

The vector may include a phenotypically selectable marker to identify host cells which contain the expression vector. Examples of markers typically used in prokaryotic
25 expression vectors include antibiotic resistance genes for ampicillin (β -lactamases), tetracycline and chloramphenicol (chloramphenicol acetyltransferase). Examples of such markers typically used in mammalian expression vectors include the gene for adenosine deaminase (ADA), aminoglycoside phosphotransferase (neo, G418), dihydrofolate reductase (DHFR), hygromycin-B-phosphotransferase (HPH), thymidine kinase (TK), and
30 xanthine guanine phosphoribosyltransferase (XGPRT, *gpt*).

In another preferred embodiment, the expression system used is one driven by the baculovirus polyhedrin promoter. The polynucleotide encoding LPAAT can be manipulated

by standard techniques in order to facilitate cloning into the baculovirus vector. See Ausubel *et al.*, *supra*. A preferred baculovirus vector is the *pBlueBac* vector (Invitrogen, Sorrento, CA). The vector carrying a polynucleotide encoding LPAAT is transfected into *Spodoptera frugiperda* (Sf9) cells by standard protocols, and the cells are cultured and processed to
5 produce the recombinant polypeptide. See Summers et al., *A Manual for Methods of Baculovirus Vectors and Insect Cell Culture Procedures*, Texas Agricultural Experimental Station.

The polynucleotides of the present invention can be expressed in any number of different recombinant DNA expression systems to generate large amounts of polypeptide.

10 Included within the present invention are LPAAT polypeptides having native glycosylation sequences, and deglycosylated or unglycosylated polypeptides prepared by the methods described below. Examples of expression systems known to the skilled practitioner in the art include bacteria such as *E. coli*, yeast such as *Pichia pastoris*, baculovirus, and mammalian expression systems such as in Cos or CHO cells.

15 The polynucleotides of the present invention can be inserted into an expression vector by standard subcloning techniques. In a preferred embodiment, an *E. coli* expression vector is used which produces the recombinant protein as a fusion protein, allowing rapid affinity purification of the protein. Examples of such fusion protein expression systems are the glutathione S-transferase system (Pharmacia, Piscataway, NJ), the maltose binding
20 protein system (NEB, Beverly, MA), the thiofusion system (Invitrogen, San Diego, CA), the Strep-tag II system (Genosys, Woodlands, TX), the FLAG system (IBI, New Haven, CT), and the 6xHis system (Qiagen, Chatsworth, CA). Some of these systems produce recombinant polypeptides bearing only a small number of additional amino acids, which are unlikely to affect the LPAAT ability of the recombinant polypeptide. For example, both the
25 FLAG system and the 6xHis system add only short sequences, both of which are known to be poorly antigenic and which do not adversely affect folding of the polypeptide to its native conformation. Other fusion systems produce proteins where it is desirable to excise the fusion partner from the desired protein. In a preferred embodiment, the fusion partner is linked to the recombinant polypeptide by a peptide sequence containing a specific
30 recognition sequence for a protease. Examples of suitable sequences are those recognized by the Tobacco Etch Virus protease (Life Technologies, Gaithersburg, MD) or Factor Xa (New England Biolabs, Beverly, MA) or enterokinase (Invitrogen, San Diego, CA).

In an embodiment of the present invention, the polynucleotides encoding LPAAT are analyzed to detect putative transmembrane sequences. Such sequences are typically very hydrophobic and are readily detected by the use of standard sequence analysis software, such as MacDNASIS (Hitachi, San Bruno, CA). The presence of transmembrane sequences is often deleterious when a recombinant protein is synthesized in many expression systems, especially in *E. coli*, as it leads to the production of insoluble aggregates which are difficult to renature into the native conformation of the polypeptide.

Accordingly, deletion of one or more of the transmembrane sequences may be desirable. Deletion of transmembrane sequences typically does not significantly alter the conformation or activity of the remaining polypeptide structure. However, one can determine whether deletion of one or more of the transmembrane sequences has effected the biological activity of the LPAAT protein by, for example, assaying the activity of the LPAAT protein containing one or more deleted sequences and comparing this activity to that of unmodified LPAAT. Assaying LPAAT activity can be accomplished by, for example, contacting the LPAAT protein of interest with the substrates LPA and fatty acyl-CoA and measuring the generation of PA or CoA, or, alternatively, measuring the formation of free CoA. Such assays for determining LPAAT activity are described in more detail below in the section describing screening assays.

Moreover, transmembrane sequences, being by definition embedded within a membrane, are inaccessible as antigenic determinants to a host immune system. Antibodies to these sequences will not, therefore, provide immunity to the host and, hence, little is lost in terms of generating monoclonal or polyclonal antibodies by omitting such sequences from the recombinant polypeptides of the invention. Deletion of transmembrane-encoding sequences from the polynucleotide used for expression can be achieved by standard techniques. See Ausubel *et al.*, *supra*, Chapter 8. For example, fortuitously-placed restriction enzyme sites can be used to excise the desired gene fragment, or the PCR can be used to amplify only the desired part of the gene.

Transformation of a host cell with recombinant DNA may be carried out by conventional techniques. When the host is prokaryotic, such as *E. coli*, competent cells which are capable of DNA uptake can be prepared from cells harvested after exponential growth phases and subsequently treated by a CaCl₂ method using standard procedures.

Alternatively, $MgCl_2$ or $RbCl$ can be used. Transformation can also be performed after forming a protoplast of the host cell or by electroporation.

When the host is a eukaryote, methods of transfection of DNA, such as calcium phosphate co-precipitates, conventional mechanical procedures, (e.g., microinjection),
5 electroporation, liposome-encased plasmids, or virus vectors may be used. Eukaryotic cells can also be cotransformed with DNA sequences encoding hLPAAT α , hLPAAT β , hLPAAT γ 1, hLPAAT γ 2, and hLPAAT δ polypeptides of the invention, and a second foreign DNA molecule encoding a selectable phenotype, such as the herpes simplex thymidine kinase gene. Another method uses a eukaryotic viral vector, such as simian
10 virus 40 (SV40) or bovine papilloma virus to transiently infect or transform eukaryotic cells and express the hLPAAT α , hLPAAT β , hLPAAT γ 1, hLPAAT γ 2, and hLPAAT δ polypeptides.

Expression vectors that are suitable for production of LPAAT polypeptides preferably contain (1) prokaryotic DNA elements coding for a bacterial replication origin and
15 an antibiotic resistance marker to provide for the growth and selection of the expression vector in a bacterial host; (2) eukaryotic DNA elements that control initiation of transcription, such as a promoter; and (3) DNA elements that control the processing of transcripts, such as a transcription termination/polyadenylation sequence. LPAAT polypeptides of the present invention preferably are expressed in eukaryotic cells, such as
20 mammalian, insect and yeast cells. Mammalian cells are especially preferred eukaryotic hosts because mammalian cells provide suitable post-translational modifications such as glycosylation. Examples of mammalian host cells include Chinese hamster ovary cells (CHO-K1; ATCC CCL61), rat pituitary cells (GH $_1$; ATCC CCL82), HeLa S3 cells (ATCC CCL2.2), rat hepatoma cells (H-4-II-E; ATCC CRL1548) SV40-transformed monkey kidney
25 cells (COS-1; ATCC CRL 1650) and murine embryonic cells (NIH-3T3; ATCC CRL 1658). For a mammalian host, the transcriptional and translational regulatory signals may be derived from viral sources, such as adenovirus, bovine papilloma virus, simian virus, or the like, in which the regulatory signals are associated with a particular gene which has a high level of expression. Suitable transcriptional and translational regulatory sequences also can
30 be obtained from mammalian genes, such as actin, collagen, myosin, and metallothionein genes.

Transcriptional regulatory sequences include a promoter region sufficient to direct the initiation of RNA synthesis. Suitable eukaryotic promoters include the promoter of the mouse metallothionein I gene (Hamer *et al.*, *J. Molec. Appl. Genet.* 1:273,1982); the TK promoter of Herpes virus (McKnight, *Cell* 31: 355, 1982); the SV40 early promoter (Benoist *et al.*, *Nature* 290:304, 1981); the Rous sarcoma virus promoter (Gorman *et al.*, *Proc. Nat'l. Acad. Sci. USA* 79:6777, 1982); and the cytomegalovirus promoter (Foecking *et al.*, *Gene* 45:101, 1980). Alternatively, a prokaryotic promoter, such as the bacteriophage T3 RNA polymerase promoter, can be used to control fusion gene expression if the prokaryotic promoter is regulated by a eukaryotic promoter (Zhou *et al.*, *Mol. Cell. Biol.* 10:4529, 1990; Kaufman *et al.*, *Nucl. Acids Res.* 19:4485, 1991).

An expression vector can be introduced into host cells using a variety of techniques including calcium phosphate transfection, liposome-mediated transfection, electroporation, and the like. Preferably, transfected cells are selected and propagated wherein the expression vector is stably integrated in the host cell genome to produce stable transformants.

Techniques for introducing vectors into eukaryotic cells and techniques for selecting stable transformants using a dominant selectable marker are described, for example, by Ausubel and by Murray (ed.), *Gene Transfer and Expression Protocols* (Humana Press 1991). Examples of mammalian host cells include COS, BHK, 293 and CHO cells.

Purification of Recombinant Polypeptides.

The LPAAT polypeptide expressed in any of a number of different recombinant DNA expression systems can be obtained in large amounts and tested for biological activity. The recombinant bacterial cells, for example *E. coli*, are grown in any of a number of suitable media, for example LB, and the expression of the recombinant polypeptide induced by adding IPTG to the media or switching incubation to a higher temperature. After culturing the bacteria for a further period of between 2 and 24 hours, the cells are collected by centrifugation and washed to remove residual media. The bacterial cells are then lysed, for example, by disruption in a cell homogenizer and centrifuged to separate the dense inclusion bodies and cell membranes from the soluble cell components. This centrifugation can be performed under conditions whereby the dense inclusion bodies are selectively enriched by incorporation of sugars such as sucrose into the buffer and centrifugation at a selective speed. If the recombinant polypeptide is expressed in the inclusion, these can be washed in any of several solutions to remove some of the contaminating host proteins, then

solubilized in solutions containing high concentrations of urea (*e.g.*, 8 M) or chaotropic agents such as guanidine hydrochloride in the presence of reducing agents such as β -mercaptoethanol or DTT (dithiothreitol). At this stage it may be advantageous to incubate the polypeptide for several hours under conditions suitable for the polypeptide to undergo a refolding process into a conformation which more closely resembles that of the native polypeptide. Such conditions generally include low polypeptide (concentrations less than 500 mg/ml), low levels of reducing agent, concentrations of urea less than 2 M and often the presence of reagents such as a mixture of reduced and oxidized glutathione which facilitate the interchange of disulphide bonds within the protein molecule. The refolding process can be monitored, for example, by SDS-PAGE or with antibodies which are specific for the native molecule. Following refolding, the polypeptide can then be purified further and separated from the refolding mixture by chromatography on any of several supports including ion exchange resins, gel permeation resins or on a variety of affinity columns.

Isolation and purification of host cell expressed polypeptide, or fragments thereof may be carried out by conventional means including, but not limited to, preparative chromatography and immunological separations involving monoclonal or polyclonal antibodies.

These polypeptides may be produced in a variety of ways, including via recombinant DNA techniques, to enable large scale production of pure, biologically active hLPAAT α , hLPAAT β , hLPAAT γ 1, hLPAAT γ 2, and hLPAAT δ useful for screening compounds for, *e.g.*, trilineage hematopoietic and anti-inflammatory therapeutic applications, and developing antibodies for therapeutic, diagnostic and research use.

Screening Assays

The hLPAAT α , hLPAAT β , hLPAAT γ 1, hLPAAT γ 2, and hLPAAT δ polypeptides of the present invention are also useful in a screening methodology for identifying compounds or compositions which affect cellular signaling of an inflammatory response. Such compounds or compositions to be tested can be selected from a combinatorial chemical library or any other suitable source (Hogan, Jr., *Nat. Biotechnology* 15:328, 1997).

This method comprises, for example, contacting hLPAAT α , hLPAAT β , hLPAAT γ 1, hLPAAT γ 2, and/or hLPAAT δ in the presence of compound and substrate for LPAAT, namely LPA and fatty acyl-CoA. These hLPAAT proteins can either be purified

prior to incubation or can be contained in extracts from a cell line or cell lines (for example, Sf9, ECV304, A549) transfected with cDNA encoding these polypeptides (West et al., *DNA Cell Biol.* 16:691, 1997). Alternatively, hLPAAT protein can be purified from transfected cells, and the protein, being a transmembrane protein, can then be reconstituted in a lipid bilayer to form liposomes for delivery into cells (Weiner, *Immunomethods* 4:201, 1994).

The effect of a compound or composition on hLPAAT α , hLPAAT β , hLPAAT γ 1, hLPAAT γ 2, or hLPAAT δ activity can be determined, for example, by measuring the generation of PA and CoA. PA can be measured by, for example, TLC methods described in Examples 3 and 7, found below. Alternatively, LPAAT activity can be assayed by detecting the formation of free CoA in reaction. CoA, which contains a free sulfhydryl-group, can be measured either by, for example, colorimetric or fluorescenic methods with sulfhydryl-specific reagents, such as, 5,5'-dithiobis-(2-nitrobenzoic acid) (DTNB) or ThioGlo (Covalent Associates, Woburn, MA). The observed effect on hLPAAT α , hLPAAT β , hLPAAT γ 1, hLPAAT γ 2, and hLPAAT δ may be either inhibitory or stimulatory.

Peptide Sequencing

Purified polypeptides prepared by the methods described above can be sequenced using methods well known in the art, for example using a gas phase peptide sequencer (Applied Biosystems, Foster City, CA). Because the proteins of the present invention may be glycosylated, it is preferred that the carbohydrate groups are removed from the proteins prior to sequencing. This can be achieved by using glycosidase enzymes. Preferably, glycosidase F (Boehringer-Mannheim, Indianapolis, IN) is used. To determine as much of the polypeptide sequence as possible, it is preferred that the polypeptides of the present invention be cleaved into smaller fragments more suitable for gas-phase sequence analysis. This can be achieved by treatment of the polypeptides with selective peptidases, and in a particularly preferred embodiment, with endoproteinase lys-C (Boehringer). The fragments so produced can be separated by reversed-phase HPLC chromatography.

Antibodies Directed to LPAAT

Antibodies to human LPAAT can be obtained using the product of an LPAAT expression vector or synthetic peptides derived from the LPAAT coding sequence coupled to a carrier (Pasnett et al., *J. Biol. Chem.* 263:1728, 1988) as an antigen. The preparation of

polyclonal antibodies is well-known to those of skill in the art. See, for example, Green et al., "Production of Polyclonal Antisera," in *Immunochemical Protocols* (Manson, ed.), pages 1-5 (Humana Press 1992). Alternatively, an LPAAT antibody of the present invention may be derived from a rodent monoclonal antibody (MAb). Rodent monoclonal antibodies to specific antigens may be obtained by methods known to those skilled in the art. See, for example, Kohler and Milstein, *Nature* 256:495, 1975, and Coligan et al. (eds.), *Current Protocols in Immunology*, 1:2.5.1-2.6.7 (John Wiley & Sons 1991). Briefly, monoclonal antibodies can be obtained by injecting mice with a composition comprising an antigen, verifying the presence of antibody production by removing a serum sample, removing the spleen to obtain B-lymphocytes, fusing the B-lymphocytes with myeloma cells to produce hybridomas, cloning the hybridomas, selecting positive clones which produce antibodies to the antigen, culturing the clones that produce antibodies to the antigen, and isolating the antibodies from the hybridoma cultures.

MAbs can be isolated and purified from hybridoma cultures by a variety of well-established techniques. Such isolation techniques include affinity chromatography with Protein-A Sepharose, size-exclusion chromatography, and ion-exchange chromatography. See, for example, Coligan at pages 2.7.1-2.7.12 and pages 2.9.1-2.9.3. Also, see Baines et al., "Purification of Immunoglobulin G (IgG)," in *Methods in Molecular Biology*, 10:79-104 Humana Press, Inc. 1992. An LPAAT antibody of the present invention may also be derived from a subhuman primate antibody. General techniques for raising therapeutically useful antibodies in baboons may be found, for example, in Goldenberg et al., international patent publication No. WO 91/11465 (1991), and in Losman et al., *Int. J. Cancer* 46:310, 1990.

Alternatively, a therapeutically useful LPAAT antibody may be derived from a "humanized" monoclonal antibody. Humanized monoclonal antibodies are produced by transferring mouse complementary determining regions from heavy and light variable chains of the mouse immunoglobulin into a human variable domain, and then, substituting human residues in the framework regions of the murine counterparts. The use of antibody components derived from humanized monoclonal antibodies obviates potential problems associated with the immunogenicity of murine constant regions. General techniques for cloning murine immunoglobulin variable domains are described, for example, by the publication of Orlandi et al., *Proc. Nat'l. Acad. Sci. USA* 86:3833, 1989. Techniques for producing humanized MAbs are described, for example, by Jones et al., *Nature* 321:522,

1986, Riechmann et al., *Nature* 332:323, 1988, Verhoeyen et al., *Science* 239:1534, 1988, Carter et al., *Proc. Nat'l Acad. Sci. USA* 89:4285, 1992, Sandhu, *Crit. Rev. Biotech.* 12: 437, 1992, and Singer et al., *J. Immun.* 150:2844, 1993, each of which is hereby incorporated by reference.

5 As an alternative, an LPAAT antibody of the present invention may be derived from human antibody fragments isolated from a combinatorial immunoglobulin library. See, for example, Barbas et al., *METHODS: A Companion to Methods in Enzymology* 2:119 1991, and Winter et al., *Ann. Rev. Immunol.* 12:433, 1994, which are incorporated by reference.

Cloning and expression vectors that are useful for producing a human immunoglobulin
10 phage library can be obtained, for example, from STRATAGENE Cloning Systems (La Jolla, CA). In addition, an LPAAT antibody of the present invention may be derived from a human monoclonal antibody. Such antibodies are obtained from transgenic mice that have been "engineered" to produce specific human antibodies in response to antigenic challenge.

In this technique, elements of the human heavy and light chain locus are introduced into
15 strains of mice derived from embryonic stem cell lines that contain targeted disruptions of the endogenous heavy chain and light chain loci. The transgenic mice can synthesize human antibodies specific for human antigens, and the mice can be used to produce human antibody-secreting hybridomas. Methods for obtaining human antibodies from transgenic mice are described by Green et al., *Nature Genet.* 7:13, 1994; Lonberg et al., *Nature*
20 368:856, 1994, and Taylor et al., *Int. Immun.* 6:579, 1994.

hLPAAT α and hLPAAT β

hLPAAT α

Search of the Genbank database of expressed sequence *tag* (dbest) using either the yeast or plant LPAAT protein sequences as probe came up with several short stretches of
25 cDNA sequences with homology to the yeast or plant LPAAT protein sequence. These cDNA sequences of interest were derived from single-run partial sequencing of random human cDNA clones projects carried out by either the WashU-Merck EST or the Genexpress-Genethon program. An example of the amino acids sequence homology between the yeast LPAAT and a human cDNA clone (dbest#102250) is shown below by
30 comparing SEQ ID NO. 3 (top amino acid sequence) with SEQ ID NO 4 (bottom amino acid sequence):

PFKKGAFHLAQQGKIPIVPVVVSNTSTLVSPKYGVFNRGCMIVRILKPISTE

* ***** * **** * * * * * *

PSNCGAFHLAVQAQVPIVPIVMSSYQDFYCKKERRFTSGQCQVRVLPVPTE

5 The top line refers to the yeast LPAAT sequence from amino acids 169 to 220 and
the bottom line refers to the homologous region from the dbest clone#102250. Identical
amino acids between these two sequences are shown in block letters with asterisks in
between

10 Accordingly, a synthetic oligonucleotide (o.BLPAT.2R), 5'-
TGCAAGATGGAAGGCGCC-3' (SEQ ID NO. 5), was made based on the complement
sequence of the conserved amino acids region, GAFHLA (SEQ ID NO. 6), of
clone#102250. o.BPLAT.2R was radiolabeled at its 5'-end using γ -³²P-ATP and T4
polynucleotide kinase as a probe in screening a λ zap human brain cDNA library
(Stratagene).

15 Screening of the cDNA library was accomplished by filter hybridization using
standard methods (*Current Protocols in Molecular Biology*, John Wiley & Sons, Inc.,
1995). Duplicate filters containing DNA derived from λ phage plaques were
prehybridized at 60 °C for 2 hr in 6X SSC (1 X SSC is 0.15 M NaCl, 0.015 M sodium
citrate, pH 7.0), 5X Denhardt's solution (1X Denhardt's solution is 0.02% Ficoll, 0.02%
bovine serum albumin, and 0.02% polyvinyl-pyrrolidone), 0.1% sodium dodecyl sulfate
20 (SDS), 50 mg/ml sonicated and denatured salmon sperm DNA. Hybridization was carried
out in the same buffer as used for prehybridization. After hybridization, the filters were
washed in 6 X SSC at 42 °C, and autoradiographed.

25 Of the approximately 1 X 10⁶ clones from the human brain cDNA library that
were screened, twelve clones were identified that hybridized with the probe in duplicate
filters. Eleven out twelve clones were enriched and recovered after a secondary screen.
Ten enriched phage samples were then converted to plasmid transformed cells by co-
infecting *E. coli* XL1-Blue with the helper phage R408 using Stratagene's recommended
procedure. Colony filter hybridization was performed and identified those colonies that
"lit up" with the probe. Seven out of the ten pools of colonies contained positive clones.
30 Two out of these seven clones, pZlpat.10 and pZlpat.11, contained inserts >2 kb.
Restriction mapping using a combination of *Sst* I, *Pst* I and *Bam*HI digests showed these
two clones contained many common fragments with respect to each other.

Nucleotide sequencing of the cDNA inserts in pZlpat.10 and pZlpat.11 was performed. Figure 1 shows the DNA sequence of the cDNA insert of pZlpat.11. The nucleotide sequence analysis and restriction mapping of the cDNA clone revealed a 5'-untranslated region of >300 bp, an open reading frame capable of encoding a 283 amino acid polypeptide, and a 3'-untranslated region of >800 bp. The initiation site for translation was localized at nucleotide positions 319-321 and fulfilled the requirement for an adequate initiation site according to Kozak (Kozak, *Critical Rev. Biochem. Mol. Biol.* 27:385-402, 1992). There was another upstream ATG at positions 131-133 with an in-phase stop codon at positions 176-178. Except with a shorter 5'-untranslated region, the cDNA insert of pZlpat.10 has the same DNA sequence as that of pZlpat.11.

The sequence of the 283 amino acid open reading frame in pZlpat.11 was used as the query sequence to search for homologous sequences in protein databases. Search of the database based on Genbank Release 90 from the National Center for Biotechnology Information (NCBI) using the blastp program showed that the protein encoded by pZlpat.11 was most homologous to the yeast and bacterial LPAATs. Figure 2 shows amino acid sequences alignment of the putative human LPAAT α coding sequence, the yeast LPAAT coding sequence, the *E. coli* LPAAT coding sequence, and the maize LPAAT coding sequence, revealing that human LPAAT α has a much more extended homology with the yeast or the *E. coli* LPAAT than with the plant LPAAT.

hLPAAT β

Search of the Genbank database (Boguski, et al., *Science* 265:1993-1994, 1994) of expressed sequence tag (dbEST) using either the yeast or plant LPAAT protein sequences as probe came up with several short stretches of cDNA sequences with homology to the yeast or plant LPAAT protein sequence. These cDNA sequences of interest were derived from single-run partial sequencing of random human cDNA clones projects carried out mainly by I.M.A.G.E. Consortium [LLNL] cDNA clones program. An example of the amino acids sequence homology between the yeast LPAAT and a human cDNA clone (dbEST#363498) is shown below:

halves of the cDNA into a full-length clone, the 560 bp *Nco* I - *Nar* I fragment from pLPAT3.5' and the 780 bp *Nar* I - *Xba* I fragment from pLPAT3.3' were inserted into the *Nco* I / *Xba* I vector prepared from pSP-luc+ (Promega, Madison, WI) via a three-part ligation to generate pSP.LPAT3.

Figure 3 shows the DNA sequence ID of the cDNA insert of pSP.LPAT3. The nucleotide sequence analysis and restriction mapping of the cDNA clone revealed a 5'-untranslated region of 39 bp, an open reading frame capable of encoding a 278 amino acids polypeptide that spans nucleotide positions 40 to 876 and a 3'-untranslated region of 480 bp (Figure 3). The initiation site for translation was localized at nucleotide positions 40-42 and fulfilled the requirement for an adequate initiation site according to Kozak (Kozak, *Critical Rev. Biochem. Mol. Biol.* 27:385-402, 1992).

The sequence of the 278 amino acid open reading frame (Figure 4) was used as the query sequence to search for homologous sequences in protein databases. Search of the database based on Genbank Release 92 from the National Center for Biotechnology Information (NCBI) using the blastp program showed that this protein was most homologous to the yeast, bacterial and plant LPAATs. Figure 5 shows amino acid sequences alignment of this putative human LPAAT β coding sequence, human LPAAT α coding, the yeast LPAAT coding sequence, the bacterial (*E. coli*, *H. influenzae*, and *S. typhimurium*) LPAAT coding sequences, and the plant (*L. douglassi* and *C. nucifera*) LPAAT coding sequences, revealing that the human LPAAT coding sequences have a much more extended homology with the yeast or the bacterial LPAAT than with the plant LPAAT.

hLPAAT γ 1, hLPAAT γ 2, or hLPAAT δ

Described below is the isolation of human LPAAT isoforms hLPAAT γ 1, hLPAAT γ 2, or hLPAAT δ , which are distinct from hLPAAT α and hLPAAT β .

Search of the Genbank database (Boguski, et al., *Science* 265:1993-1994, 1994) of expressed sequence tag (dbEST) using the maize form-I LPAAT protein (Brown, et al., *Plant Mol. Biol.* 26: 211-223, 1994) sequences as probes resulted in the identification of several short stretches of human cDNA sequences with homology to the maize LPAAT protein sequence. These cDNA sequences of interest were derived from single-run partial sequencing of random human cDNA clones projects carried out mainly by I.M.A.G.E. Consortium [LLNL] cDNA clones program. An example of the amino acids sequence

homology between the maize LPAAT and a human cDNA clone (GenBank#T55627) is shown below:

```

5      150 GLQRLKDFPRPFWLALFVEGTRF 172
          ..... .. :. ....
          GLRRLSDYPEYMWFLLYCEGTRF

```

The top line refers to the maize LPAAT sequence from amino acids 150 to 172 and the bottom line refers to the homologous region from the dbEST clone with GenBank#T55627. Identical and conserved amino acids between these two sequences are shown as double dots and single dots, respectively, in the row in between. In order to determine if these human cDNA clones with homology to maize LPAAT but distinct from human LPAAT α or LPAAT β indeed encoded human LPAAT, it was undertaken to isolate the full-length cDNA clone, insert it into an expression vector, and to test if cells transformed or transfected with the cDNA expression vector produced more LPAAT activity.

Accordingly, a synthetic oligonucleotides, 5'-GACTACCCC GAGTACATG TGGTTTCTC-3' (oLPTg_1F) was ordered (Life Technologies, Gaithersburg, MD) based on the coding region corresponding to amino acids DYPEYMWFL of clone GenBank#T55627. oLPTg_1F was used in combination with a reverse vector primer (o.sport.1R), 5'-CTAGCTTATA ATACGACTCA C-3', for amplification of the 3'-region of potential LPAAT sequences from a pCMV.SPORT human leukocyte cDNA library (Life Technologies, Gaithersburg, MD). A 1,000 bp PCR fragment derived from o.sport.1R and oLPTg_1F amplification was cut with Xho I before inserting in between the Sma I and Xho I of pBluescript(II)SK(-) (Stratagene, LaJolla, CA) to generate the plasmid pLPTg_3'. Nucleotide sequencing (performed by the Seattle Biomedical Research Institute sequencing service) analysis of the cDNA inserts from plasmid pLPTg_3' showed it contained sequences that matched with the clone GenBank#T55627 as well as extensive homology with the C-terminal end of the maize LPAAT amino acids sequence (Brown, et al., *Plant Mol. Biol.* 26: 211-223, 1994). To isolate the 5'-portion of this putative LPAAT clone, a synthetic oligonucleotide, 5'-CACATGTCCG CCTCGTACTT CTTC-3' (oLPTg_1R), complementary to a region just downstream of the Bam HI site of the cDNA within generate the plasmid pLPTg_3' was used in

combination with a forward vector primer (o.sport.1), 5'- GACTCTAGCC
TAGGCTTTTG C-3' for amplification of the 5'-region from a pCMV.SPORT human
leukocyte cDNA library (Life Technologies, Gaithersburg, MD). The PCR fragments
generated were cut with Acc65 I and BamH I before inserting in between the Acc65 I and
5 BamH I of pBluescript(II)SK(-) (Stratagene, LaJolla, CA). DNA sequence analysis of two
cDNA clones containing, respectively, a 980 bp and a 770 bp Acc65 I - BamH I inserts
showed they contained sequences that overlapped with the cDNA insert of pLPT γ _3' as
well as extensive homology with the N-terminal end of the maize LPAAT amino acids
sequence. The DNA sequence of these two cDNA clones diverged at the 5'-regions,
10 suggesting the presence of two alternatively spliced variants with one variant (pLP γ 1_5')
containing an additional 62 amino acids at the N-terminus relative to the other one
(pLP γ 2_5'). To assemble the two halves of each cDNA into full-length clones, the 980
bp Acc65 I - BamH I fragment from pLP γ 1_5' or the 770 bp Acc65 I - BamH I fragment
from pLP γ 2_5' were inserted into the Acc65 I / Xho I vector prepared from
15 pBluescript(II)SK(-) (Stratagene, LaJolla, CA) along with the 870 bp Bam HI - Xho I
fragment from pLPT γ _3' via a three-part ligation to generate pSK_LP γ 1 and pSK_LP γ 2,
respectively.

Figure 9 shows the DNA and the translated sequence (LPAAT- γ 1) of the cDNA
insert of pSK_LP γ 1. The nucleotide sequence analysis and restriction mapping of the
20 cDNA clone revealed a 5'-untranslated region of 183 bp with two ATGs and an in-phase
stop codon, an open reading frame capable of encoding a 376 amino acids polypeptide that
spans nucleotide positions 184 to 1314 and a 3'-untranslated region of 345 bp. The
initiation site for translation was localized at nucleotide positions 184-186 and fulfilled the
requirement for an adequate initiation site (Kozak, *Critical Rev. Biochem. Mol. Biol.*
25 27:385-402, 1992).

Figure 10 shows the DNA and the translated sequence (hLPAAT γ 2) of the cDNA
insert of pSK_LP γ 2. The nucleotide sequence analysis and restriction mapping of the
cDNA clone revealed a 5'-untranslated region of 232 bp with two upstream ATGs with in-
phase stop codons, an open reading frame capable of encoding a 314 amino acids
30 polypeptide that spans nucleotide positions 133 to 1177 and a 3'-untranslated region of 346
bp. The initiation site for translation was localized at nucleotide positions 233-235 and

Example 1

This example illustrates an experiment to determine if the human LPAAT α clone encodes a protein with LPAAT activity, an *E. coli* vector expressing the human LPAAT α as a fusion protein with β -galactosidase was transformed into a LPAAT minus strain of *E. coli* to see if it would complement the defect in *E. coli*. Specifically, the 840 bp *Bgl* II-*Nco* I fragment, which spans the coding region of human LPAAT α from amino acid 68 to beyond the stop codon, derived from pZplat.11 was inserted into a *Bgl* II / *Nco* I digested cloning vector pLitmus28 (Evans et al., *BioTechniques* 19:130-135, 1995) to generate the plasmid p28BgN. This plasmid is expected to express the human LPAAT α as a fusion protein containing the first 16 amino acids of β -galactosidase and the last 216 residues of the human LPAAT α coding sequence using the *lac* promoter in pLitmus28. This plasmid was transformed into the *E. coli* strain JC201 (obtained from Dr. Jack Coleman, Louisiana State University). JC201 (Coleman, *Mol. Gen. Genet.* 232:295-303, 1992; Nagiec et al., *J. Biol. Chem.* 268:22156-22163, 1993; and Brown et al., *Plant Mol. Biol.* 26:211-223, 1994) is deficient in LPAAT activity due to mutation in the *plsC* locus. This mutation leads to a temperature-sensitive phenotype that causes JC201 to grow slowly at 37 °C, almost not at all at 42 °C, and not at all at 44 °C. JC201 transformed with p28BgN was able to grow normally at 44 °C when compared to the wild type strain JC200 (*plsC*⁺), while JC201 transformed with pLitmus28 vector was not able to support growth at 44 °C. These data suggest that the putative human LPAAT α cDNA isolated here does possess LPAAT activity, as the last 216 amino acids of this cDNA is sufficient to complement the defective LPAAT gene (*plsC*) in JC201.

Example 2

To see if the putative human LPAAT β clone encodes a protein with LPAAT activity, an *E. coli* vector expressing this human LPAAT β as a direct product was transformed into a LPAAT minus strain of *E. coli* to see if it would complement the defect in *E. coli*. Specifically, the 1350 bp *Nco* I - *Xba* I fragment from pSP.LPAT3, which spans the entire coding region from amino acid 1 to beyond the stop codon, was inserted into a *Nco* I / *Xba* I digested cloning vector pKK388-1 (Clontech, Palo Alto, CA) to generate the plasmid pTrc.LPAT3. This plasmid was transformed into the *E. coli* strain JC201 (obtained from Dr. Jack Coleman, Louisiana State University). JC201 (Coleman, *Mol.*

Gen. Genet. 232:295-303, 1992) is deficient in LPAAT activity due to mutation in the *plsC* locus. This mutation leads to a temperature-sensitive phenotype that causes JC201 to grow slowly at 37 °C, almost not at all at 42 °C, and not at all at 44 °C. JC201 transformed with pTrc.LPAT3 was able to grow normally at 44 °C when compared to the wild type strain JC200 (*plsC*⁺), while JC201 transformed with pKK388-1 vector was not able to support growth at 44 °C. These data suggest that the putative human LPAAT β cDNA isolated here does possess LPAAT activity, as the putative protein product of this cDNA is able to complement the defective LPAAT gene (*plsC*) in JC201.

Example 3

This example illustrates a group of experiments to see if overexpression of this human LPAAT α would have any effect on mammalian cells. The entire cDNA insert (~2,300 bp) from pZplat.11 was cleaved with Asp718 I and Xho I for insertion into the mammalian expression vector pCE9 to generate pCE9.LPAAT1. pCE9 was derived from pCE2 with two modifications. The 550 bp BstY I fragment within the elongation factor-1a (EF-1a) intron of pCE2 was deleted. The multiple cloning region of pCE2 between the Asp718 I and BamH I site was replaced with the multiple cloning region spanning the Asp718 I and Bgl II sites from pLitmus28. The plasmid pCE2 was derived from pREP7b (Leung, et al., *Proc. Natl. Acad. Sci. USA*, 92: 4813-4817, 1995) with the RSV promoter region replaced by the CMV enhancer and the elongation factor-1a (EF-1a) promoter and intron. The CMV enhancer came from a 380 bp Xba I-Sph I fragment produced by PCR from pCEP4 (Invitrogen, San Diego, CA) using the primers 5'-GGCTCTAGAT ATTAATAGTA ATCAATTAC-3' and 5'-CCTCACGCAT GCACCATGGT AATAGC-3'. The EF-1a promoter and intron (Uetsuki, et al., *J. Biol. Chem.*, 264: 5791-5798, 1989) came from a 1200 bp Sph I-Asp718 I fragment produced by PCR from human genomic DNA using the primers 5'-GGTGCATGCG TGAGGCTCCG GTGC-3' and 5'-GTAGTTTTCA CGGTACCTGA AATGGAAG-3'. These 2 fragments were ligated into a Xba I/Asp718 I digested vector derived from pREP7b to generate pCE2.

pCE9.LPAAT1 DNA was transfected into several mammalian cell lines, including A549 cells, ECV304 cells (American Type Culture Collection, Rockville, MD), two human cell line that would produce IL-6 and TNF upon stimulation with IL-1b and murine TNF and 293-EBNA cells (Invitrogen, San Diego, CA). pCE9.LPAAT1 was digested with

BspH I before electroporating into these cell lines with a Cell-Porator™ (Life Technologies, Gaithersburg, MD) using conditions described previously (Cachianes, et al., *Biotechniques* 15:255-259, 1993). After adherence of the transfected cells 24 hours later, the cells were grown in the presence of 200 µg / ml Hygromycin B (Hyg) (Calbiochem, La Jolla, CA) to select for cells that had incorporated both plasmids. Hyg-resistant clones that expressed LPAAT mRNA at a level more than 20 fold higher relative to untransfected cells based on Northern Blot analysis (Kroczeck, et al., *Anal. Biochem.* 184: 90-95, 1990) were selected for further study.

Figure 6 compares the LPAAT activity in A549 cells and in A549 cells transfected with pCE9.LPAAT1 DNA using aTLC assay. This screening assay for LPAAT activity in cell extracts was based on a fluorescent assay using fluorescent lipid substrates (Ella, et al., *Anal. Biochem.* 218: 136-142, 1994). Instead of using the PC-substrate, BPC (Molecular Probes, Eugene, OR), a synthetic PC that contains an ether linkage at the SN1 position with a fluorescent Bodipy moiety incorporated into the end of the alkyl-chain at the SN1 position, BPC was converted to Bodipy-PA using cabbage phospholipase D (Sigma, St. Louis, MO). Bodipy-PA was then converted to Bodipy-LPA using snake venom phospholipase A2. The Bodipy-LPA obtained was purified by preparative TLC for use in the LPAAT assay. The assay was carried out in total cell extracts resuspended in lysis buffer (Ella, et al., *Anal. Biochem.* 218: 136-142, 1994) supplemented with 0.5 mM ATP, 0.3 mM MgCl₂, 100 µM oleoyl-CoA and 10 µM Bodipy LPA. The samples were incubated for 30 min before loading onto TLC plates.

Lane 1 refers to Bodipy LPA incubated with buffer only without any cell extract added. Lane 9 refers to BPC treated with cabbage phospholipase D for generating a Bodipy-PA marker. Lanes 2 and 4 refer to Bodipy LPA incubated with control A549 cell extracts with or without lipid A, respectively. Lanes 3 and 5 refer to Bodipy LPA incubated with A549 cell extracts transfected with pCE9.LPAAT1 DNA with or without lipid A, respectively. Figure 3 shows A549 cells transfected with the LPAAT cDNA (lanes 3 and 5) contain much more LPAAT activity than those of control cells (lanes 2 and 4) as evidenced by the increased conversion of Bodipy-LPA to Bodipy-PA. Addition of lipid A to the cell extracts has little effect on LPAAT activity (lanes 2 vs 4 and 3 vs 5). A549 cell extract also contains a phosphohydrolase activity that converts Bodipy-LPA to Bodipy-monoalkylglycerol (lanes 2 to 5). Interestingly, A549 cells overexpressing

LPAAT (lanes 3 and 5) have less of this activity compared to control cells (lanes 2 and 4), suggesting this phosphohydrolase prefers LPA to PA as substrate. There is also an increase of DAG in transfected cells (lanes 3 and 5) compared to control cells (lanes 2 and 4) possibly due to partial conversion of the PA formed to DAG from this endogenous phosphohydrolase.

Example 4

To see if the expressed LPAAT cDNA clone described here would also use other glycerol-lipids that contain a free-hydroxyl group at the SN2 position, the cell extracts were incubated with the substrates NBD-lysoPC (lanes 6 and 7) and NBD-monoacylglycerol (MAG) (lanes 10 and 11) to see if there is increased conversion to lysoPC and DAG, respectively. Lane 8 and 12 refer, respectively, to NBD-lysoPC and NBD-MAG incubated with buffer only without any cell extract added. TLC analysis shows little difference in the lipid profile between the transfected and control cells (lanes 7 vs 6, lanes 11 vs 10), suggesting the cloned LPAAT enzyme uses LPA as the preferred substrate. It is likely that the acyltransferases for lysoPC (Fyrst, et al., *Biochem. J.* 306:793-799, 1995) and for MAG (Bhat, et al., *Biochemistry* 34: 11237-11244, 1995) represent different enzymes from the LPAAT described here.

Example 5

pCE9.LPAAT1 DNA was transfected into A549 cells (American Type Culture Collection, Rockville, MD), a human cell line that would produce IL-6 and TNF upon stimulation with IL-1 β and murine TNF. pCE9.LPAAT1 was digested with *Bsp*HI before electroporating into A549 cells with a Cell-PoratorTM (Life Technologies, Gaithersburg, MD) using conditions described previously (Cachianes, et al., *Biotechniques* 15:255-259, 1993). After adherence of the transfected cells 24 hours later, the cells were grown in the presence of 200 μ g/ml Hygromycin B (Hyg) (Calbiochem, La Jolla, CA) to select for cells that had incorporated both plasmids. A Hyg-resistant clone that expressed LPAAT mRNA at a level more than 20 fold higher relative to untransfected A549 cells based on Northern Blot analysis (Kroczeck et al., *Anal. Biochem.* 184:90-95, 1990) was selected for further study.

A comparison of the production of TNF (Figure 7) and IL-6 (Figure 8) between A549 cells transfected with pCE9.LPAAT1 and control A549 cells after stimulation with IL-1 β and murine TNF shows A549 overexpressing LPAAT produces >5 fold more TNF and >10 fold more IL-6 relative to untransfected A549 cells, suggesting that overexpression of LPAAT would enhance the cytokine signaling response in cells. Development of compounds that would modulate LPAAT activity should therefore be of therapeutic interest in the field of inflammation.

Example 6

Construction of pC9LPT γ 1 and pC2LPT δ : The primers 5'-ggcccgggtacc ATGGGCCTG CTGGCCTTC C-3' (oLP γ 1_1F) and 5'-taactcCTCGAG TTATTCCTT TTTCTTAAA CTC-3' (oLP γ 1_1R) were used to amplify the 1100 bp Acc65 I - XhoI fragment by PCR from the template pSK_LPg1. The fragment generated was then inserted into a Acc65 I / Xho I digested pCE9 (West, et al., *DNA Cell Biol.* 6: 691-701, 1997) expression vector to make pC9LPT γ 1. Similarly, the primers 5'-atggtggtaccacc ATGGACCTC GCGGGACTG CTG-3' (oLPT δ _1F) and 5'-GGAGGATATc tAGAgGCCAC CAGTTC-3' (oLPT δ _1R) were used to amplify the 1100 bp Acc65 I - Xba I fragment by PCR from the template #H18562. The fragment generated was then inserted into a Acc65 I / Nhe I digested pCE2 (West, et al., *DNA Cell Biol.* 6: 691-701, 1997) expression vector to make pC2LPT δ .

Example 7

Expression of hLPAAT γ 1 and hLPAAT δ in mammalian cells. Plasmids pC9LPT γ 1 or pC2LPT δ were stably transfected into endothelial ECV304 cells (American Type Culture Collection, Rockville, MD). Specifically, pC9LPT γ 1 or pC2LPT δ were digested with BspH I before electroporating into these cell lines with a Cell-PoratorTM (Life Technologies, Gaithersburg, MD). After adherence of the transfected cells 24 hours later, the cells were grown in the presence of 500 μ g / ml Hygromycin B (Hyg) (Calbiochem, La Jolla, CA) to select for cells that had incorporated plasmids. Hyg-resistant clones that expressed LPAAT- γ 1 or LPAAT- δ mRNA at a level more than 10 fold higher than that of cells transfected with pCE9 or pCE2 vector, based on Northern Blot analysis, were selected for further study.

Figure 13 compares the LPAAT activity in ECV304 cells stably transfected with the expression plasmids for LPAAT- α (pCE9.LPAAT- α), LPAAT- β (pCE9.LPAAT- β) DNA, LPAAT- γ 1 (pC9LPT γ 1), LPAAT- δ (pC2LPT δ), or the control vector (pCE9). This screening assay for LPAAT activity in cell extracts was based on the conversion of

5 [14C]oleoyl-CoA to [14C]PA using a TLC assay. The assay was carried out in total cell extracts resuspended in lysis buffer (Ella, et al., *Anal. Biochem.* 218: 136-142, 1994) supplemented with 50 μ M [14C]oleoyl-CoA and 200 μ M LPA. The samples were incubated for 10 min, extracted from chloroform, before loading onto TLC plates. Lanes 1 and 2 refer to [14C]oleoyl-CoA and LPA incubated with cell extract transfected with

10 LPAAT- α plasmid; lanes 3 and 4, with LPAAT- β plasmid; lanes 5 and 6, with LPAAT- γ 1 plasmid; lanes 7 and 8, with LPAAT- δ plasmid; and lanes 9 and 10, with control vector. ECV304 cells transfected with LPAAT- α or - β cDNA (lanes 1 to 4) contain more than 3 and 20 times, respectively, LPAAT activity when compared to those of control cells (lanes 9 and 10) as evidenced by the increased conversion of [14C]oleoyl-CoA to [14C]PA. Cells

15 transfected with LPAAT- δ cDNA (lanes 7 and 8) contain about 2.5 times more LPAAT activity than those of control cells (lanes 9 and 10), whereas cells transfected with LPAAT- δ cDNA show no increase in activity when compared to those of control cells (lanes 9 and 10).
